ABSTRACT

Parking management in city and commercial areas is terribly inefficient and prompt largely by difficulty in space usage, bulky manual processes, and inconvenience to its end users. This project proposes a Smart Parking System that incorporates state-of-the-art technologies such as ANPR, IoT sensors, and SMS messages to overcome those difficulties. The entry of the vehicle is automated using ANPR license plate scanning and based on the real-time availability from IoT sensors provides dynamic allocation of slots. It sends the details of the slot and the payment link to the users' SMS. For commercial vehicles, a QR code facilitates slot selection and payment. A web-based dashboard empowers parking operators to track slot occupancy, monitor payments, and oversee system performance. The exit process is fully automated, ensuring gates open only after payment verification. By streamlining parking operations, this system optimizes space utilization, enhances user experience, and simplifies fee management, making it an ideal solution for modern parking challenges.

CHAPTER 1

1. INTRODUCTION

1.1 GENERAL

The Rapid urbanization and a growing number of vehicles have placed large burdens on the efficient management of parking spaces in urban and commercial areas. Traditional, largely man-based, parking systems operate with several inherent shortcomings, such as ineffective use of space, waiting periods extending to minutes, and real-time monitoring of available slots. This inefficiency leads to frustrated users, traffic congestion, and loss of income to the parking operators.

Advanced technologies such as Automatic Number Plate Recognition (ANPR), Internet of Things (IoT), and real-time communication systems are changing the face of parking management in urban areas. All these can be easily accessed to build fully automated parking systems, minimizing human intervention, avoiding misuse of space, and providing maximum convenience to users.

It will focus on developing a Smart Parking System, integrating ANPR for automated vehicle identification, IoT sensors to monitor the slot in real-time, and SMS notifications for the communication of the user. The proposed system is seamless for both users and operators.

At entry, ANPR technology captures the plate number of the vehicle and verifies it against the system database. IoT sensors installed at each parking slot detect its status in real time and update slot availability status dynamically. Users receive SMS notifications with their allocated slot details, payment links, or QR codes for further action.

A web-based dashboard empowers the parking operators through an enhancement that offers real-time usage of slots, payment records, and system performance. The exit process can fully be automated in that only after confirmation of payment are the vehicles allowed to leave. The system improves the management of parking by streamlining operations, minimizing waiting times, and enhancing transparency in making payments.!

This report will discuss the design, development, and implementation of the Smart Parking System in detail to demonstrate how it can bring about significant change in the management of parking within urban and commercial environments. The ANPR-combined IoT and SMS-based notification system provides an efficient means to address the modern challenges of parking, opening possibilities for smarter, more sustainable urban infrastructure.

With vehicle ownership rising, not to mention the scarcity of parking infrastructures, it is becoming challenging to park in cities and business areas. Traditional parking management systems are usually manual and, therefore, inefficient. They entail waiting for long hours on the parking lot, maximum unutilized parking spaces, and bothered customers. All these translate to loss of revenue from more traffic piling up in the roads for parking operators.

This project introduces a Smart Parking System that integrates Automatic Number Plate Recognition (ANPR), Internet of Things (IoT) sensors, and SMS notifications to streamline parking management. The system automates vehicle entry, allocates parking slots dynamically based on real-time availability, and ensures efficient fee collection via SMS-based payment links.

1.2 OBJECTIVE

It is trying to give you a comprehensive roadmap towards achieving the goals of your Smart Parking System-to be efficient, convenient, and sustainable. Do let me know if you need further elaboration or additional points. The system intends to

1. Automate Parking Management

The key objective of the proposed design is to minimize manual intervention and create an automated parking system. ANPR technology can identify incoming vehicles without a physical ticketing process or mandatory registration. In this case, exit processing will integrate with payment validation to create a smooth user experience and a faster turnaround for patrons.

2. Optimize Parking Space Utilization

By The system can monitor real-time availability by integrating IoT sensors in each parking slot. This allows for dynamic and efficient slot allocation to maximize available parking space. This objective will also serve to minimize the situations where spaces are left vacant through human error or mismanagement.

3. Enhance User Convenience

This system was designed to make the parking experience hassle-free for its users. Following entry, users are automatically assigned a slot- SMS notification containing slot details and payment options. For commercial vehicles, QR codes will be provided for self-selection of slots, simplifying payment processing. It saves one a lot of waiting time, reduces confusion, and generally increases satisfaction levels.

4. Ensure Secure and Transparent Payments

Integrating a secure payment gateway, transactions are therefore secure, easy to process, and traceable. Users can pay through SMS payment links or QR codes. It makes the parking process quick and cashless. The system also keeps detailed records of all transactions for transparency and auditing.

5. Monitor Parking Operations in Real Time

The end provides complete oversight of the system for the empowerment of parking operators through a web-based dashboard. This dashboard is designed with real-time slot occupancy, payment statuses, and system health information. Operators can make better decisions in real-time with these insights and identify latent system troubles for improvement in efficiency.

6. Reduce Traffic Congestion

The system aims at easing traffic congestion in and around parking areas by speeding up entry and exit processes. Automated slot allocation and real-time updates further reduce the time spent on search efforts, reduce queues, and improve the flow of traffic in busy urban locations.

7. Improve Scalability and Flexibility

The system is adaptable to be implemented across various parking scenarios, from small parking lots up to large urban infrastructures. Its modularity makes it adaptable to different requirements, such as additional technologies like mobile apps or an EV charging system.

8. Enhance Security and Accountability

This system prevents unauthorized parking or misuse of reserved spaces as it cross-verifies the parking slot with assigned vehicles through IoT and ANPR. Thus, each vehicle is parked in its designated slot, upholding accountability and enhancing the security of the parking area.

9. Promote Sustainability

One of the system's wider purposes is to aid in environmental sustainability. Through the reduction of time for searching parking by drivers, it reduces the consumption of fuel and emissions produced by greenhouse gases. Besides this, through the digital transactions and the auto procedures, it reduces the paper waste while increasing eco-friendly operations.

1.3 EXISTING SYSTEM

Most of the parking systems in place are characterized by old manual processes, semi-automated mechanisms, or partially digital solutions that failed to keep up with growing urbanization and vehicle growth in addition to users' increasingly high expectations. High populations in some areas still depend on manual systems where entry is managed through parking attendants for slot allocation and collection of payment. These systems are inherently inefficient, because their execution leads to delaying queues during peak hours due to the time taken to issue tickets and to process payments. Human mistakes in slot management lead to misallocation and underutilized parking spaces and disputes over fees. Additionally, the nature of cash payments hampers operations, and at the same time, leaves avenues for leakage and corruptive practices, making these systems highly unreliable.

Slightly improved from previous types, semi-automated systems still have serious limitations: they include elementary technologies such as automatic ticket dispensers or barrier gates. In most cases, customers then need to look for vacant slots on their own because such systems do not avail real-time slot monitoring and allocation. Payment processing is conducted at kiosks or at exit points, usually causing congestion and queues, even when it's busy. While these systems cut some of the burden on operators, they do not offer the efficiency and user friendliness that modern parking facilities entail.

More advanced parking solutions are based on RFID technology or tags/cards that automatically allow entry and exit to registered vehicles. Though they offer faster processing for recurrent users, they may not be proper solutions for public or mixed-use parking areas because they entirely eliminate one-time or occasional visitors. They do not support real-time slot tracking and dynamic allocation. The downside is in scalability, because the infrastructure needed for RFID implementation is significant.

The parking systems available today are mainly dominated by obsolete traditional manual methods, and half-automatic, or half-digital, methods, and half those available as mobile applications. The latter enables one to check the availability of parking and even book a parking space well before one arrives. However, sometimes the booking fails because the apps update inaccurately or in real-time in some cases, depending on whether the updates depend on user manual or semi-auto entry rather than IoT-enabled sensors. Similarly, these systems also have no optimization of entry and exit processes because the users still need to validate their bookings or payments manually through physical check points. In addition, user familiarity with mobile apps limits their adoption through internet connectivity further reducing their suitability for various user environments.

In all these systems, traffic congestions are a constant problem, since entry/exit points are not optimized in terms of fast processing and vehicles often queue up while waiting for tickets, searching for a slot or payment. All these delays have also environmental concerns like increased fuel consumption and emissions, particularly in urban regions. Without real-time monitoring, operators can have limited visibility into slot occupancy, leading to inefficient use of space with lost revenue opportunities. Many existing systems are also guilty of a lack of transparency and accountability in payment processing because manual systems are prone to errors and fraud, while semi-automated solutions do not provide for comprehensive auditing capabilities.

Another major weakness lies in the scalability of the current solutions. With growth in metropolitan cities, the parking requirements do not scale with it, and traditional systems are unable to grow up to larger infrastructures or add new developments such as EV charging stations, predictive analysis for demand forecasting, or more advanced security measures. This inflexibility makes them inappropriate for the needs of the contemporary city, commercial complex, and smart urban infrastructure.

Summary Parking systems currently in place do not adequately meet a number of primary goals: efficiency, real-time tracking of patrons, user convenience, traffic management, scalability, and sustainability. The systems have inadequately utilized advanced technologies such as ANPR, IoT sensors, and automated notifications due to the significant demands being made by modern parking facilities.

This is a reminder that parking systems require a holistic, technology-based solution that not only addresses existing inefficiencies but also prepares for future challenges, ensuring smoother operations, better user experiences, and sustainable management.

Manual solutions remain unable to address the growing demands associated with urbanization, vehicle growth, and user expectations. Manual parking systems continue to be prevalent in many regions; entry is managed and slots allocated by the attendant, who receives payments. These systems are basically inefficient because they introduce delays during peak hours as it takes time to issue tickets and make payments. Humans make mistakes in managing the parking slots that allocate them wrongly, waste parking spaces, and bring out disputes over fees. Moreover, cash payments rely on cash-for-service, which negatively impacts operations because it slows processes, and revenue leakage and even corruption opportunities are created, thus making these systems highly unreliable.

Semi-automated systems, which combine basic technologies like automated ticket dispensers or barrier gates, are a slight improvement but suffer from tremendous limitations. These systems usually require manual searching after entering the parking lot for available slots, since they do not have mechanisms to monitor or allocate slots in real-time. Payments are also usually made at kiosks or upon exit, which hinders smooth and orderly processing, quite commonly causing congestion and delays, particularly at busy hours. While these systems reduce some of the burdens on the operators, they fail to provide the level of efficiency and user convenience required by modern parking facilities.

More recent advancements include RFID-based parking systems, which utilize radio-frequency identification tags or cards to automate entry and exit for registered vehicles. These systems allow faster processing for regular users but exclude casual or one-time visitors, making them unsuitable for public or mixed-use parking areas. Moreover, they do not incorporate real-time slot tracking or dynamic allocation, and their scalability is limited due to the infrastructure required for RFID deployment.

20

1.3 PROPOSED SYSTEM

The proposed Smart Parking System aims to revolutionize traditional parking management through the latest technologies, such as Automatic Number Plate Recognition, IoT sensors, and real-time communication tools. The system, which is entirely automated, efficient, and user-friendly, is designed to completely transform existing systems, thereby providing users with a seamless experience and allowing parking operators to maximize space usage, streamline operations, and ensure secure revenue management.

The system starts at the entrance to the parking lot, where the ANPR technology scans and identifies the vehicle's license plate number. This automated process obviates the issuance of manual tickets; it is time-consuming and often prone to error. By automatically recording the details of the vehicle, the system captures a unique log entry that tracks the vehicle appropriately for the duration of its stay in the park. This real-time capture not only speeds up entry but also provides an additional layer of security due to the digital record created for every vehicle admitted onto the premises. On identification of a vehicle, the system allocates a parking spot on the fly using real-time availability data from IoT-enabled sensors installed at each parking slot. Sensors continuously monitor the occupancy status of all slots and relay this information to the central system. This ensures that vehicles are guided to the nearest available slot, minimizing search time and optimizing space usage. Dynamic allocation prevents scenarios where certain areas are overcrowded while others remain underutilized, maximizing the efficiency of the parking facility. To enhance user convenience, the system sends an SMS notification to the vehicle owner upon successful slot allocation. The notification includes details of the assigned slot, navigation instructions, and a secure payment link for the parking fee.

The IoT sensors track slot occupancy as well as authenticate the parking of the vehicle in its allotted slot. On the off chance of a mismatch or any unauthorized parking, the system flags the issue on the web-based dashboard enabling the operators to rectify the matter. This will ensure that the parking facility is utilized correctly without any subsequent conflict or misuse of reserved slots.

One of the bright features is the cashless payment integration into the system, thus eliminating the need to collect fees manually. A user can, therefore, make a payment through the link sent via SMS or directly by using the QR code scanned at entry. The system checks on the status of payment before opening the gates to exit. The exit process is totally automated. Once it confirms completion of the payment, only then will the gate open; it always ensures smooth and secure transitions. This streamlined process significantly reduces delays, especially during peak hours, and enhances the overall user experience.

A web-based dashboard will be the nerve center of parking operations, centrally reporting to all control requirements in a parking facility. The dashboard will have real-time inputs on slot occupation, vehicle logs, and revenues made. The system can monitor the performance of the system, payment statuses, and provide detailed reports for auditing and optimization purposes. Such historical data can be analyzed to try to identify usage patterns and help operators improve their operational decisions based on data rather than instinct.

The system is designed to be scalable and adaptable, making it suitable for a wide range of parking situations. Whether it's a small commercial lot, a large urban parking structure, or a mixed-use facility, the modular architecture ensures effortless implementation and future expansion. It allows integration with features such as electric vehicle (EV) charging stations, enhanced mobile app interfaces for user engagement, or predictive analytics demand forecasting.

The proposed system reduces congestion within and around parking facilities by automating slot allocation, payment, and exit processes.

The vehicle is promptly directed to the available slots, thereby minimizing time spent in searching for a parking slot. The system, apart from improving traffic flow, also enhances users' parking experience and reduces environmental impacts caused by idling vehicles.

The system reduces unnecessary driving within parking lots, lowering fuel consumption and carbon emissions. The use of digital payments lowers the uses of paper-based ticketing, hence aligning it with eco-friendly practices. Real-time monitoring, thereby efficient operations, implies the proper utilization of resources, contributing to sustainable urban development.

The security of the users and the operators is guaranteed with ANPR, IoT sensors, and automated payment systems. Vehicular entry and exit are logged to create a very transparent record that rules out disputes over payments or unauthorized access. Operators get full visibility into slot usage and revenue generation, thereby taking responsibility and preventing revenue leakage.

The system is designed to make it as smooth and effortless an experience as possible for the users. Automated tasks such as ticketing, payment, and navigation save time and increase convenience in using the system. The SMS alert and the QR code are features that offer users convenient access, ensuring that casual and regular users are catered to by the system.

CHAPTER 2

2. LITERATURE SURVEY

The literature survey for the Smart Parking System project gives an in-depth review of existing research, technologies, and approaches in the development of smart parking solutions by making use of Automatic Number Plate Recognition (ANPR), IoT sensors, mobile apps, and SMS notifications as ways to enhance parking management systems. ⁵ Smart parking solutions must optimize the utilization of available parking spaces and reduce congestion in a manner that maximizes a positive overall user experience.

As cities grow, increasing available parking spaces requires efficient management of limited parking, thus increasing the need for automated and real-time parking management systems. ANPR technology is one of the cornerstones of smart parking systems. It automates the process of reading in vehicle number plates. As Chien et al. (2020) indicate, ANPR allows for automated entry and exit of vehicles, thereby rendering parking systems much more efficient and minimizing the amount of human intervention required, saving time spent verifying manually as well as obviating the use of physical tokens. This technology is usually combined with centralized databases to provide vehicles with a proper identification process, thus smoothifying the parking operations.

IoT sensors also form a crucial part in the smart parking system. With sensors like ultrasonic, infrared, and magnetic deployed in parking spaces, real-time data on space availability is collected and transmitted to a central management system. Alam et al. (2019) demonstrated how IoT sensors allow for continuous monitoring of parking space usage, providing real-time updates on whether spaces are occupied or available. These sensors minimize the time spent by drivers searching for a free parking spot and reduce traffic congestion in parking areas. Additionally, the sensor data is accessible through a mobile app, allowing users to see which spaces are available and book them in advance.

A mobile app is considered a basic feature for smart parking systems, as this

allows users not only to check the availability of parking but also to handle payments, receive notifications, and reserve parking spots. The integration of mobile payment systems has revolutionized the parking experience as cashless transactions, as highlighted in Singh and Jain (2018). Mobile applications have now enabled easy payment through a credit card, digital wallets, and payment links, thereby ensuring a smooth transaction process without the need for physical payment terminals or cash. The functionality of SMS notifications further improves the experience for users by providing them with the real-time information about reserved parking slots, reminders, payment confirmations, and instructions. This service provides a way in which the user can manage the experience even when they are not actively using the app. QR codes have even become a convenient option for commercial vehicles, allowing an easy availability of parking space, making payments, and also managing transactions pertaining to parking. Gupta and Kumar (2018) underlined the use of QR codes in solving the parking problem, particularly in commercial or high-traffic areas, by providing a user with a quick scan code to acquire access to parking services.

Despite this advancement, there are several challenges that need to be overcome for smart parking systems to be adopted at large scales.

Sharma et al. (2021) reported that the high initial cost of setting up smart parking infrastructure such as camera costs, sensor cost, and in-house software development may prevent smaller businesses or municipalities from adopting such systems.

Another challenge associated with data security is critical since vehicle data and payment information are highly sensitive information.

Cybersecurity concerns must be addressed to protect user privacy and prevent fraudulent activities within parking systems. In addition, the adoption rate for intelligent parking is slow, especially in regions where digital literacy is low or the users are not well accustomed to automatic systems. User-centric design and intuitive interfaces play a key role in breaking this barrier. Recently, Lee and Park (2019) conducted some studies and state that the ease of use, accessibility to all age groups, and

clear instructions are the possible factors to increase user acceptance. The future will be driven by ¹¹ the installation of artificial intelligence (AI) and machine learning (ML) technologies in the next generation of smart parking. Zhang et al. (2020) examined the utilization of AI for predicting parking demand using real-time traffic and historical data to enable proactive management of space availability in the parking system.

Another way predictive analytics can enhance efficiencies in operations is by providing optimal parking spots to users, reducing traffic congestion, and utilizing parking more efficiently.

Another new trend is a use of the blockchain for payment security: blockchains can provide secure, transparent, and tamper-proof transactions, which can foster trust with users if smart parking systems become digital. Another potential outcome from blockchain-based decentralization of transactions might be better control of parking fees and lower administrative costs. Conclusion The literature review clearly concludes that smart parking systems are rapidly transforming and evolving from innovations in integrating new technologies to seek higher efficiency, decreased congestion, and greater convenience for users.

While the smart parking system has its merits in the efficiency, convenience for the users, and effective use of space, high costs, data security issues, and time-consuming adoption ³ form formidable barriers to the full implementation of this technology. Emerging technologies such as AI, ML, and blockchain could help address these challenges and lead to better enhancement of the effectiveness of smart parking systems, making them more reliable and user-friendly in the future.

CHAPTER 4

4.1 METHODOLOGIES:

The methodology of the Smart Parking System project is primarily about using advanced technologies like Automatic Number Plate Recognition (ANPR), IoT sensors, QR codes, and mobile applications for designing an efficient, automated, and user-friendly parking management system. This system will further ⁵ optimize the usage of the parking space, reduce congestion, enhance the ease of users, and manage the fees or charges on parking properly. All methodology components discussed below in details will be used to develop this Smart Parking System:

1. System Architecture and Design

8

ANPR Cameras: Automatic Number Plate Recognition cameras are installed at entry and exit points of the parking area. These cameras capture images of vehicle license plates as they enter or exit from the parking facility. Advanced image processing algorithms (Optical Character Recognition) are then applied to extract the license plate number from the captured image.

IoT Sensors: Parking spaces are equipped with IoT sensors that detect whether the spot is occupied or vacant. These sensors are often ultrasonic, infrared, or magnetic, and they provide real-time occupancy data, transmitting it to a centralized system for processing.

Centralized Server: A central server is the brain of the entire system, which collects and analyzes the data received from the ANPR cameras and IoT sensors. This continuously keeps it updated about the status of parking spaces, vehicle details, and user requests. It also takes care of user queries, reservations, and payments all through the mobile app.

Mobile Application/Web Portal: It is the user interface which facilitates the driver to interact with the system.¹⁸ Using the mobile application/web portal, users can check for parking availability, reserve a spot, pay, and get real-time notifications.

2. Automatic Number Plate Recognition (ANPR)

Image Capture: The ANPR camera captures the image of the license plate whenever a vehicle enters or exists the parking area. Care is taken to place the camera in such a position that it captures an unobstructed, clear view of the plate of the vehicle.

After the capture of an image, OCR or Optical Character Recognition technology processes the image to extract the number of the license plate. Algorithms analyze the image for the specific patterns and characters relating to the alphanumeric characters on the license plate.

Database Matching The extracted license plate number is matched against a database to see if the vehicle is allowed to park within the area. If it is registered in the system, the gate will open automatically; otherwise, the system may prompt the user for registration or deny entry.

This process is efficient, with faster and reliable speed; it enables smooth entry and exit without manual intervention, which eliminates waiting time and improves the user experience overall.

3. IoT Sensor Integration

Sensor Deployment: Ultrasonic or magnetic sensors are installed on each parking spot. Ultrasonic sensors calculate distance traveled between the sensor and the vehicle mounting on top of it, to determine whether a space is occupied. Magnetic sensors detect changes in the magnetic field when a vehicle is found occupying the parking space.

The data from the sensors is fed into a central server through a wireless network, such as Wi-Fi, LoRaWAN, or ZigBee. The data is transmitted in real-time.

The data is constantly synchronized and updated in the mobile application or web portal, so users can see live parking availability, reducing the search time to grab a free spot.

4. Mobile App and Web Interface

The user-facing element of the Smart Parking System is the mobile app and web portal, which ensure a seamless interaction between the parking system and users.

Methodology for App Development:

Real-Time Availability: The application will communicate with a central server to provide real-time parking availability. Users can identify available spots in various areas of the parking facility and even get a map showing where they are and closest available spaces.

Booking and Reservation: Users can book up a parking spot via mobile app or web portal. Once a reservation is done, the system will automatically assign the user to a particular parking spot, and the status of which shall be updated in real time.

Payment Integration: The integrated payment gateway, such as credit/debit cards, Google Pay, Apple Pay, and other mobile wallets, allows the users to pay for their parking within the mobile app. The app will generate a digital receipt and provide a link for payment confirmation.

Notifications: Once a spot is booked, the user will receive an SMS or push notification confirming the reservation details, including the parking spot number, entry/exit time, and payment link.

User Experience: The application is simple, making it very easy for users to navigate, book, and pay for parking in minimal steps.

5. QR Code System for Commercial Vehicles

The system for commercial vehicles avails QR code technology to facilitate ease of entry into parking slots and payment processing. The methodological approach is:

QR Code Generation: Following reservation by a commercial vehicle, the system creates a unique QR code connected with the reserved place. The code carries all information, such as the parking slot, reservation time, and payment link.

QR Code Scanning: The user, in the process of entering or leaving the parking facility, scans a code at the entrance or exit gate to gain access or pay for parking. The manual entry or ticketing is eradicated.

Seamless Payment: It further directly connects to the payment system, enabling commercial vehicles to make payments on the spot. That way, the parking and payment procedure will become a lot faster.

6. Payment System Integration

Smart Parking integrates a secure mobile payment solution to enable a cashless and seamless transaction experience. This methodology includes the following elements:

Payment Gateway Integration: The system will integrate popular payment gateways, like Stripe, PayPal, Google Pay, or Apple Pay, that allow users to pay for parking directly from their smartphones.

Real-Time Payment Confirmation: Once a user has successfully made their payment, confirmation is also relayed to the user by an SMS or app notifications to reflect that the transaction was successful.

Transaction Security: The system uses end-to-end encryption for the transactions made, so that all of them are secure and protected from unauthorized usage to obtain one's payment information.

7. Data Security and Privacy

No user data is permitted in the Smart Parking System without full observance of the following strict guidelines:

Encryption: All sensitive information, including vehicles, personal details, and payment details, will be encrypted when transmitting and after storing in the database.

Access Control Only sensitive data will be viewed, with strong authentication protocols applied to users and administrators.

Legal and Industry Compliance: The system will be compliant with the local data privacy laws and industry standards in protecting user data, ensuring that it will be handled with the highest level of security.

8. Testing and Deployment

Unit Testing: Each module, that is, ANPR, IoT sensors, mobile application, and payment integration, goes through high intensity unit testing for all correctness.

Integration Testing: After the individual parts pass testing, these are then integrated into a single system, and integration testing assures the system works well without problems. User testing involves testing the system with real users to make sure it is intuitive, secure, and easy to use.

MODULES

1. ANPR (Automatic Number Plate Recognition) Module:

Real-time images of vehicles are taken with ANPR cameras at entry and exit points of the parking facility. The cameras perform under varying conditions of lighting and environment; thus, they perform correctly every time, even during the day or at night. These images contain the vehicle number plate as a key identifying and logging the vehicle. Once an image is captured, image processing algorithms are applied to detect the license plate and isolate it from the rest of the vehicle's image. These algorithms focus on identifying the exact location of the license plate, handling different font types, plate sizes, and environmental factors (e.g., rain, glare, or dirt). In the OCR process, characters are extracted from a detected license plate. The OCR system reads the image and decodes the alphanumeric characters to machine-readable text, so that the system can identify the vehicle based on its license plate number. For every entry and exit event, the occurrence is logged in the central database. The details captured include the vehicle's license plate number, the time at which it was entering or exiting, and the parking spot assigned, for tracking and analysis purposes. These data work as a base for online management of the parking system.

2. IoT Sensor Module:

For every parking spot, IoT sensors (which could be ultrasonic or magnetic) are used to determine if there is a car present. The status of each parking space occupied or available is continuously monitored by the sensors. The deployment of such sensors guarantees the parking system's capability to track parking space availability in real-time. When the sensor detects a vehicle in the parking space, it communicates the occurrence to the central system, thus updating the parking space's status. Sensors do work with remote communication protocols such as Wi-Fi, LoRaWAN, or Bluetooth. So, data can be transmitted in real time without the need for physical wiring. The sensor system continuously sends data to the central control system. If a vehicle leaves the spot, the sensor updates the status of that spot as vacant.

3. Centralized Control and Data Management Module

It aggregates the data coming from all sources, that is ANPR cameras, IoT sensors, and user actions, so collected data is consolidated for real-time monitoring in a centralized platform. This aggregation helps in understanding system-wide performance, occupancy rates, and transaction histories.

All the necessary information regarding vehicles, users, payments, and parking transactions is stored in the cloud-based database. The system ensures that the data becomes up-to-date and can be accessed remotely for monitoring, reporting, and system management. The centralized dashboard helps administrators to monitor the status of the parking lot in real-time, which includes information about the presence of parking space and sensor health along with payment transactions, in order to maintain smooth operations and immediate troubleshooting in case of any issues.

4. User Interface Module (Mobile App/Web Portal) :

Users can either register through the mobile app or through the web portal with contact details, vehicles, and payment preferences to have their first access to parking services without having to input the details for every visit. Real-time parking space availability is indicated in the mobile app or web portal based on data from IoT sensors. Users can view vacant spaces, and reserve a space in advance to avoid last-minute search time on parking. Users can opt for a preferred parking space by clicking it through the user interface. Once a space is chosen, the system will calculate the parking price, and the user can pay from that by using an integrated payment gateway like credit card, debit card, mobile wallet, or other digital wallet services.

Once a confirmation for the reservation is issued, information about the parking spot, time of reservation, and payment details are promptly communicated to the user. The services also remind the users about the time of expiration of their parking sessions, thus ensuring they take action before the lapse of their time.

5. QR Code Module for Commercial Vehicles

To commercial vehicles such as delivery vans, trucks, etc., the system provides a special kind of QR code and associates that with the reserved parking spot. This code contains important details such as allotted spot, entry time, and payment details. Once the commercial vehicle reaches the entrance, the driver scans the QR code from the gate with a scanner provided by the system. On scanning, the system cross-verifies the reservation of the vehicle and permits the vehicle to access the parking lot without further manual checks.

The payment mechanism is also facilitated by the QR code. Commercial vehicles can pay through the mobile application or scan the code at the terminal to clear their parking charges. This eliminates waiting time and allows for easy egress.

6. Payment Gateway Module

The system can integrate with numerous available payment channels, such as Stripe, PayPal, Google Pay, and Apple Pay. This allows the system to be able to reach a broad range of user preferences and regional area. After the preferred method of payment has been selected, the system will automatically handle the transaction through safe processing and transaction confirmation. Payment details are encrypted to ensure security, hence preventing unwanted access to the sensitive information. The payment gateway follows the highest standards of security measures, such as SSL/TLS encryption and, thus, compliant with PCI-DSS. These measures protect user financial data from potential breach.

7. Real-Time Parking Management Module

The In the IoT sensors, data on occupancy flows into a centralized system; this updated real-time status keeps the parking lot informed in terms of available spots and can hence be utilized more effectively. The dynamic distribution of parking by the system maximizes the use of a parking space given its real-time occupancy. For instance, an allocation priority for users with special needs or during peak hours to closer spots near the entrance can optimize it better.

It will utilize predictive analytics to space out parking for peak times. It may forecast what peak hours were in the past and amend the parking allocation mechanism.

8. Admin Dashboard Module

The It also enables the operators to oversee the entire parking facility in real time. Admins can view the occupancy status of all spots and keep track of user activity to ensure that the parking system is running smoothly. Admins can check payments made by users, find any pending payments, and generate financial reports for auditing purposes and record-keeping.

This way, all transactions are accounted for in a justified manner. The admin module also can be used to manage user accounts such as editing vehicle information, processing refunds, or resolving disputes.

The user's feedback with ratings can also be viewed by admins to enhance the service. In cases of errors, there is an alert activated by the system, which reaches the administrator for immediate response. More so, the system logs are kept for troubleshooting, diagnostics, and identification of potential improvements.

9. Exit Gate Control and Validation Module

At the exit, the ANPR cameras scan the vehicle's license plate and authenticate its payment status. Only vehicles that paid successfully will be allowed to leave the parking lot to avoid chaos and security breaches in the system. The exit system is a fully integrated module with the ANPR module. Immediately the vehicle's license plate is read, the system automatically checks if payment has been made.

In case payment can't be confirmed, the gate remains closed until the payment is verified. Once the payment gets validated, the gate opens automatically. This auto mechanism allows vehicles to exit through gates without human intervention and thus decrease wait times and improve the user experience.

10. Reporting and Analytics Module

These meters track metrics, such as peak parking times, spot utilization, and user activity, which are given to administrators to optimize parking space management and to plan for future improvements. The financial reporting feature generates detailed revenue reports that, while including total amounts collected, payment methods used, and payments that need to be made, are critical for the financial auditing process to ensure that the revenues are correctly collected. Through admin access, one can get user feedback regarding their experience of the system in actual use. This user feedback is used to adjust and make improvements to the system's functionality for better user satisfaction.

CHAPTER 5

5.1 CONCLUSION AND WORKSPACE

The system will have a key impact on changing the face of parking management because most issues, such as inefficiency, no real-time data, and user inconvenience, could be tackled. It would automatically cover all processes from parking entry to exit with the use of advanced technologies like ANPR, IoT sensors, and digital payment systems. This innovation drastically reduces human intervention, eliminates manual errors, and enhances the user experience by providing real-time updates on parking availability, automated slot allocation, and secure payment options. The system's real-time monitoring capabilities ensure that parking space utilization is optimized to the fullest.

IoT sensors continuously track the status of each parking spot, transmitting occupancy data to a central database. This facility will enable proper control over parking allotments and tracking through the ANPR system. Further enhancing user convenience, cloud-based management platforms and user interfaces may be accessible through mobile apps and web portals for checking availability, reserving spots, and making payments anywhere. Moreover, the presence of advanced facilities such as QR code access for commercial automobiles as well as automated gate controls at entry and exit points decreases delay and increases operational efficiencies. Modular design makes the system scalable to be adapted to environments such as shopping malls, campuses of various corporations, airports, and residential complexes. The admin dashboard acts as a powerful workspace for parking lot managers because it offers detailed views into parking lot utilization, financial transactions, and the operational health of the parking lot. Detailed analytics reports can be generated to plan future expansions, address peak usage periods, and enhance overall efficiency.

From a workspace perspective, the project in question combines hardware components—which could be ANPR cameras, IoT-enabled parking sensors, and gate automation systems—into a robustly built software infrastructure.

The software is integrated with AI-powered algorithms to recognize the

license plate, cloud-based data management for real-time update, and secure payment processing platforms in accordance with industrial standards. The developers and administrators cooperate under diverse conditions, such as high traffic, varying environmental settings, and peak usage times, to ensure the system performs optimally. Thorough testing is conducted to provide reliability, accuracy, and user satisfaction.

There is the Smart Parking System approach by addressing modern urban problems, particularly in combating growing traffic congestion, inefficient utilization of parking areas, and dissatisfaction with its operation.

This finds its place in smart city visions by aiming towards automation, sustainability, and efficiency in operations. In the future, such a system may be integrated with predictive analytics to provide demand forecasting, dynamic pricing models in a way that maximizes revenues, and connection with EV-charging stations to serve the environmentally conscious drivers. This project not only upgrades current parking management techniques but also provides a foundation on which to build innovations in urban mobility and infrastructure.

5.2 FOR PHASE 2

Phase 2 Phase 2: Enhancement of features that expand the functional design of the system to adapt for large-scale deployment to meet the demand of modern parking infrastructure. This phase starts with a comprehensive mobile application compatible with both Android and iOS platforms.

The application will help users check actual parking slot availability, book slots in advance, make safe payments, and receive updated information on the status of booking. Live tracking will also be used to maintain interactive maps that update users on the live location and current status of parking slots. Improved navigation and decision-making will be achieved for the users. Secure payment gateways will also be used for seamless and safe financial transactions. They would also allow various modes of payment, including credit and debit cards, mobile wallets, UPI, and region-specific payment methods.

For commercial vehicles, the system will automatically create specific QR codes during the booking process. The resulting QR codes will enable easy and swift entry and slot selection within the parking lot. This saves time to an extent and makes things easier for the process to take place without unnecessary waiting times. It would especially be helpful for fleet operators and logistics providers that require streamlined parking access. An advanced admin dashboard will be designed to empower parking lot managers with real-time monitoring and decision-making tools.

This dashboard will provide detailed analytics on parking trends, occupancy rates, revenue generation, and feedback from users. Administrators will be able to track peak usage times, identify underutilized spaces, and optimize operations based on data-driven insights. Predictive analytics will be integrated into the system to predict parking demand by analyzing historical data patterns.

This capacity shall allow the administrators to allocate resources accordingly, plan for peak traffic requirements, and implement dynamic pricing strategies to maximize revenue while ensuring satisfaction in user base.

To ensure scalability and reliability, the system's architecture will be optimized to handle larger parking facilities and high-traffic conditions. Advanced load balancing mechanisms will distribute database and server workloads evenly, preventing system crashes and ensuring smooth performance even during peak usage. The integration of failover systems and redundancy protocols will further enhance reliability, minimizing downtime and ensuring continuous operation. Comprehensive testing in real-world environments will be a critical component of Phase 2.

Rigorous testing will be performed for different scenarios of traffic, environmental conditions, and peak usage periods. The results from both users and administrators will be collected and analyzed to identify areas of improvement, which will be incorporated into the final system to ensure the highest usability and efficiency of use.

The culmination of Phase 2 will deliver a robust, user-friendly Smart Parking System, fully capable of supporting modern urban infrastructure. The system would

feature advanced real-time monitoring capabilities, predictive analytics, secure payments, and a scalable architecture that sets the highest benchmark in parking management.

This phase also sets the foundation for future improvements, like incorporating EV charging stations, AI-based traffic management, and dynamic pricing models, and is, therefore, a forward-looking solution for evolving needs in smart cities.
